# The Web as a Client-Server System; TCP/IP intro

§2.1 100,000 feet  
• Client-server (vs. P2P)

§2.2 50,000 feet  
• HTTP & URIs

§2.3 10,000 feet  
• XHTML & CSS

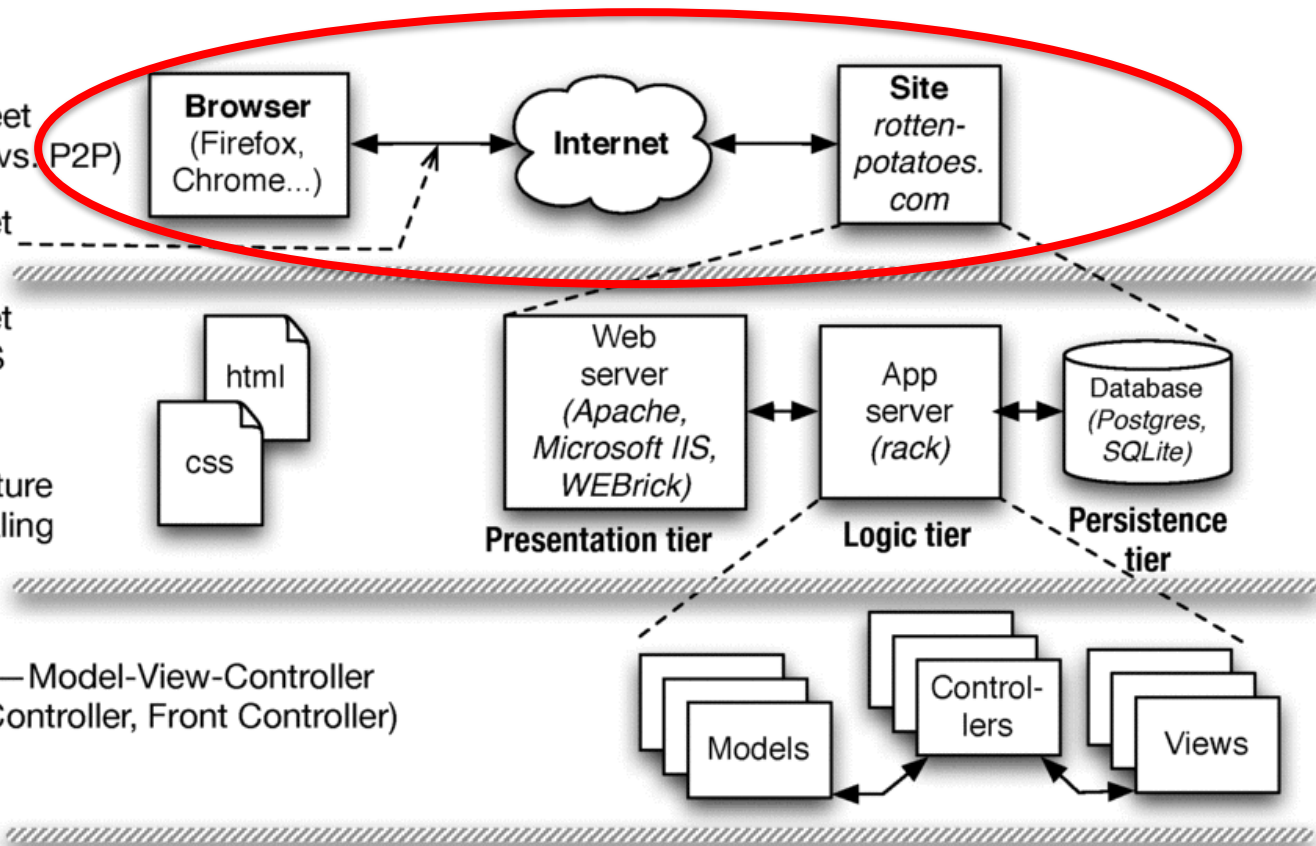

§2.4 5,000 feet  
• 3-tier architecture  
• Horizontal scaling

§2.5 1,000 feet—Model-View-Controller  
(vs. Page Controller, Front Controller)

§2.6 500 feet: Active Record models (vs. Data Mapper)

§2.7 500 feet: RESTful controllers (Representational  
State Transfer for self-contained actions)

§2.8 500 feet: Template View (vs. Transform View)

• **Active Record** • **REST** • **Template View**

• **Data Mapper** • **Transform View**

# Web at 100,000 feet

- The web is a *client/server* architecture
- It is fundamentally *request/reply oriented*

# Client-Server vs. Peer-to-Peer

- High-level architecture of the overall system
  - Soon we'll talk about architecture "inside" boxes
- Client & server each *specialized* for their tasks
  - Client: ask questions on behalf of users
  - Server: wait for & respond to questions, serve many clients
- Design Patterns capture common structural solutions to recurring problems
  - Client-Server is an *architectural pattern*

# Nuts and bolts: TCP/IP protocols

- IP (Internet Protocol) *address* identifies a physical network interface with four *octets*, e.g. **128.32.244.172**
  - Special address **127.0.0.1** is “this computer”, named **localhost**, even if not connected to the Internet!
- TCP/IP (Transmission Control Protocol/Internet Protocol)
  - IP: no-guarantee, best-effort service that delivers *packets* from one IP address to another
  - TCP: make IP reliable by detecting “dropped” packets, data arriving out of order, transmission errors, slow networks, etc., and respond appropriately
  - TCP *ports* allow multiple TCP apps on same computer
- Vint Cerf & Bob Kahn: 2004 Turing Award for Internet architecture & protocols, incl. TCP/IP

**GET /snu/**            **GET /snu/**  
**HTTP/0.9 200 OK**            **HTTP/0.9 200 OK**

# Web at 100,000 feet

- The web is a *client/server* architecture
- It is fundamentally *request/reply oriented*
- Domain Name System (DNS) is another kind of server that maps *names* to *IP addresses*

Now that we're talking, what do we say?

# Hypertext Transfer Protocol

- an *ASCII-based request/reply protocol* for transferring information on the Web
- *HTTP request* includes:
  - *request method* (**GET**, **POST**, etc.)
  - Uniform Resource Identifier (URI)
  - HTTP protocol version understood by the client
  - *headers*—extra info regarding transfer request
- *HTTP response* from server
  - Protocol version & Status code =>
  - Response headers
  - Response body

## **HTTP status codes:**

2xx — *all is well*

3xx — *resource moved*

4xx — *access problem*

5xx — *server error*

# Cookies

- Observation: *HTTP is stateless*
- Early Web 1.0 problem: how to guide a user “through” a flow of pages?
  - use IP address to identify returning user?
    - ✗ public computers, users sharing single IP
  - embed per-user junk into URI query string?
    - ✗ breaks caching
- Quickly superseded by *cookies*

# Client Pull vs. Server Push

- WebSockets and HTML5 have some support for allowing the server to push updated content to the client
  - Periodic polling
- True server push – allow the server to initiate connection to the client to wake it up when new information is available

# HTML, CSS, JavaScript

- HTML
  - Describes and defines the content of a webpage
- CSS (Cascading Style Sheets)
  - Describes how HTML elements are to be displayed on screen, paper, or in other media.
- JavaScript

# JavaScript

- A programming language that is run by most modern browsers
- A high-level, dynamic, weakly typed, object-based, and interpreted programming language
- Alongside HTML and CSS, JavaScript is one of the three core technologies of the web client side
- It can be used to control web pages on the client side of the browser, server-side programs, and even mobile applications.

# Progression for the JavaScript Community

- From plain scripts
  1. Adding module systems – maintainability, avoiding namespace pollution, reusability
  2. Adding compilers (transpilers)
    1. Writing in a language that "thinks" the way you do makes you more productive
    2. Use next generation JavaScript, today
    3. FB Babel, MS TypeScript compiler
  3. Adding type systems
    1. MS Typescript - a superset that compiles down to JavaScript — although it feels almost like a new statically-typed language in its own right
    2. FB Flow - an open-source static type checking library, incrementally add types to your JavaScript code

# TypeScript

- A super-set of JavaScript
- Add classical object-oriented semantics
- Types
- Classes
- Interfaces
- Inheritance
- Modules
- Generics

# Client Application Framework

- Easily implement interactive web applications
- Client-side MVC framework
- Angular: a framework for building client applications in HTML and either JavaScript or a language like TypeScript that compiles to JavaScript.
- React/Redux: Javascript Library for Building User Interfaces

# 3-tier shared-nothing architecture & scaling

§2.1 100,000 feet  
• Client-server (vs. P2P)

§2.2 50,000 feet  
• HTTP & URIs

§2.3 10,000 feet  
• XHTML & CSS

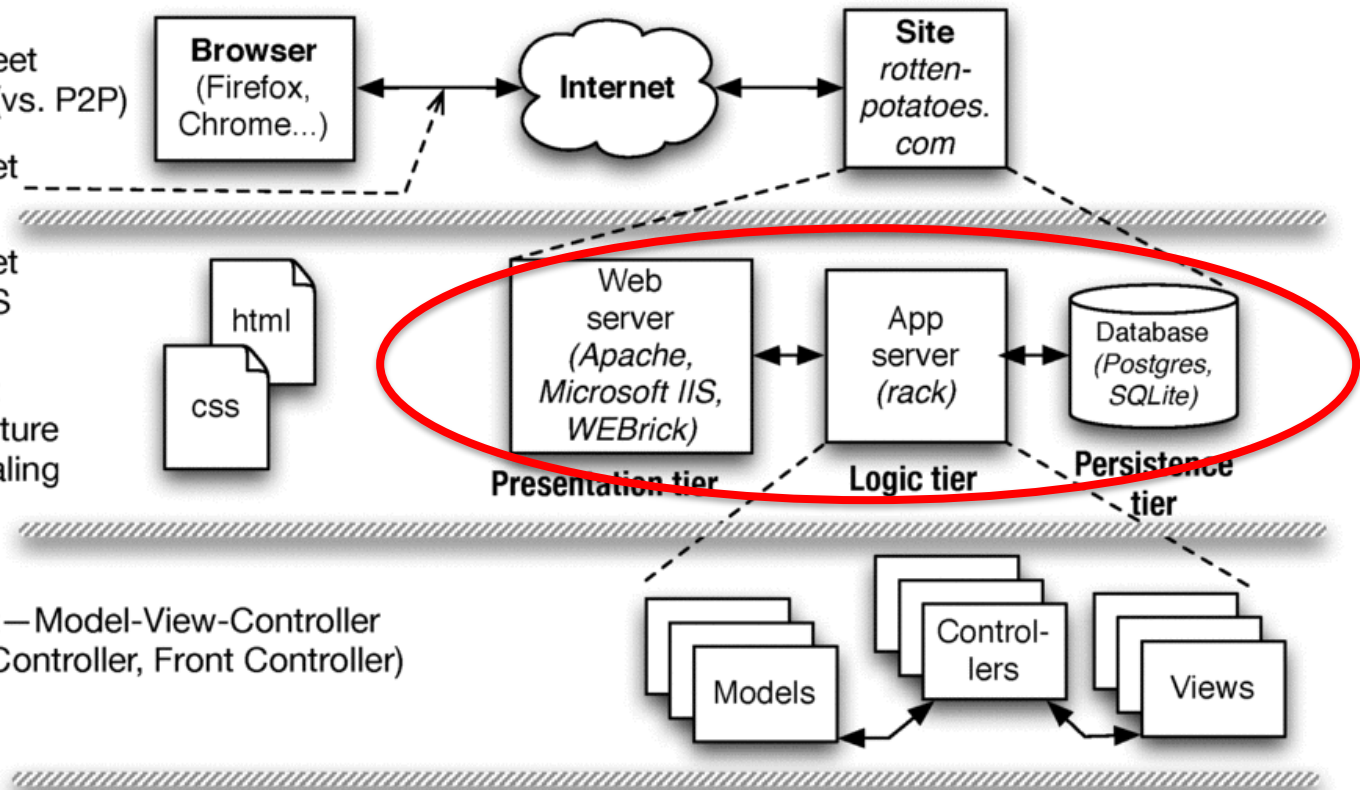

§2.4 5,000 feet  
• 3-tier architecture  
• Horizontal scaling

§2.5 1,000 feet—Model-View-Controller  
(vs. Page Controller, Front Controller)

§2.6 500 feet: Active Record models (vs. Data Mapper)

§2.7 500 feet: RESTful controllers (Representational  
State Transfer for self-contained actions)

§2.8 500 feet: Template View (vs. Transform View)

• **Active Record** • **REST** • **Template View**

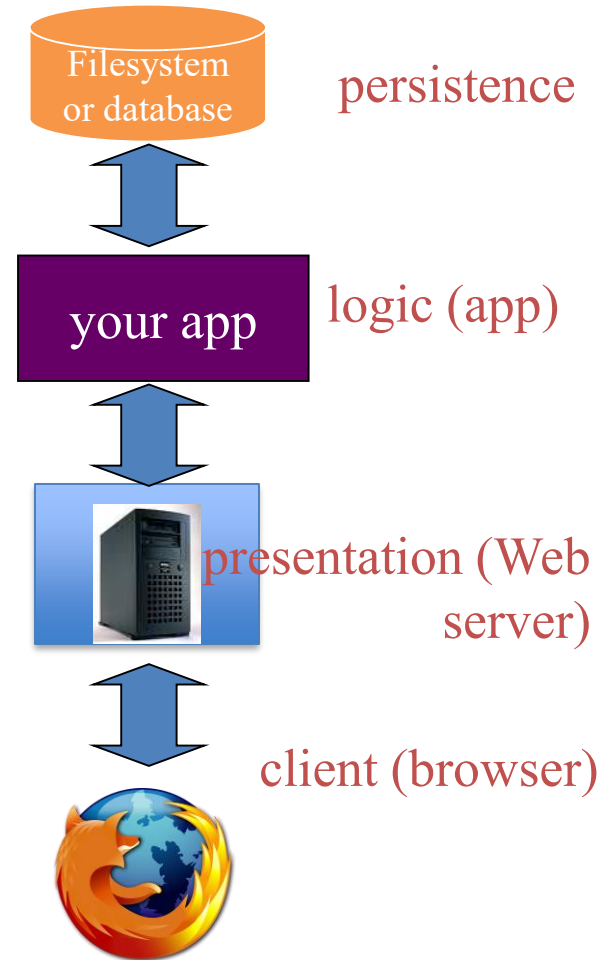

• **Data Mapper** • **Transform View**

# Dynamic content generation

- In the Elder Days, most web pages were (collections of) plain old files
- But most interesting Web 1.0/e-commerce sites *run a program* to generate each “page”
- Originally: templates with embedded code “snippets”
- Eventually, code became “tail that wagged the dog” and moved out of the Web server

# Sites that are really programs (SaaS)

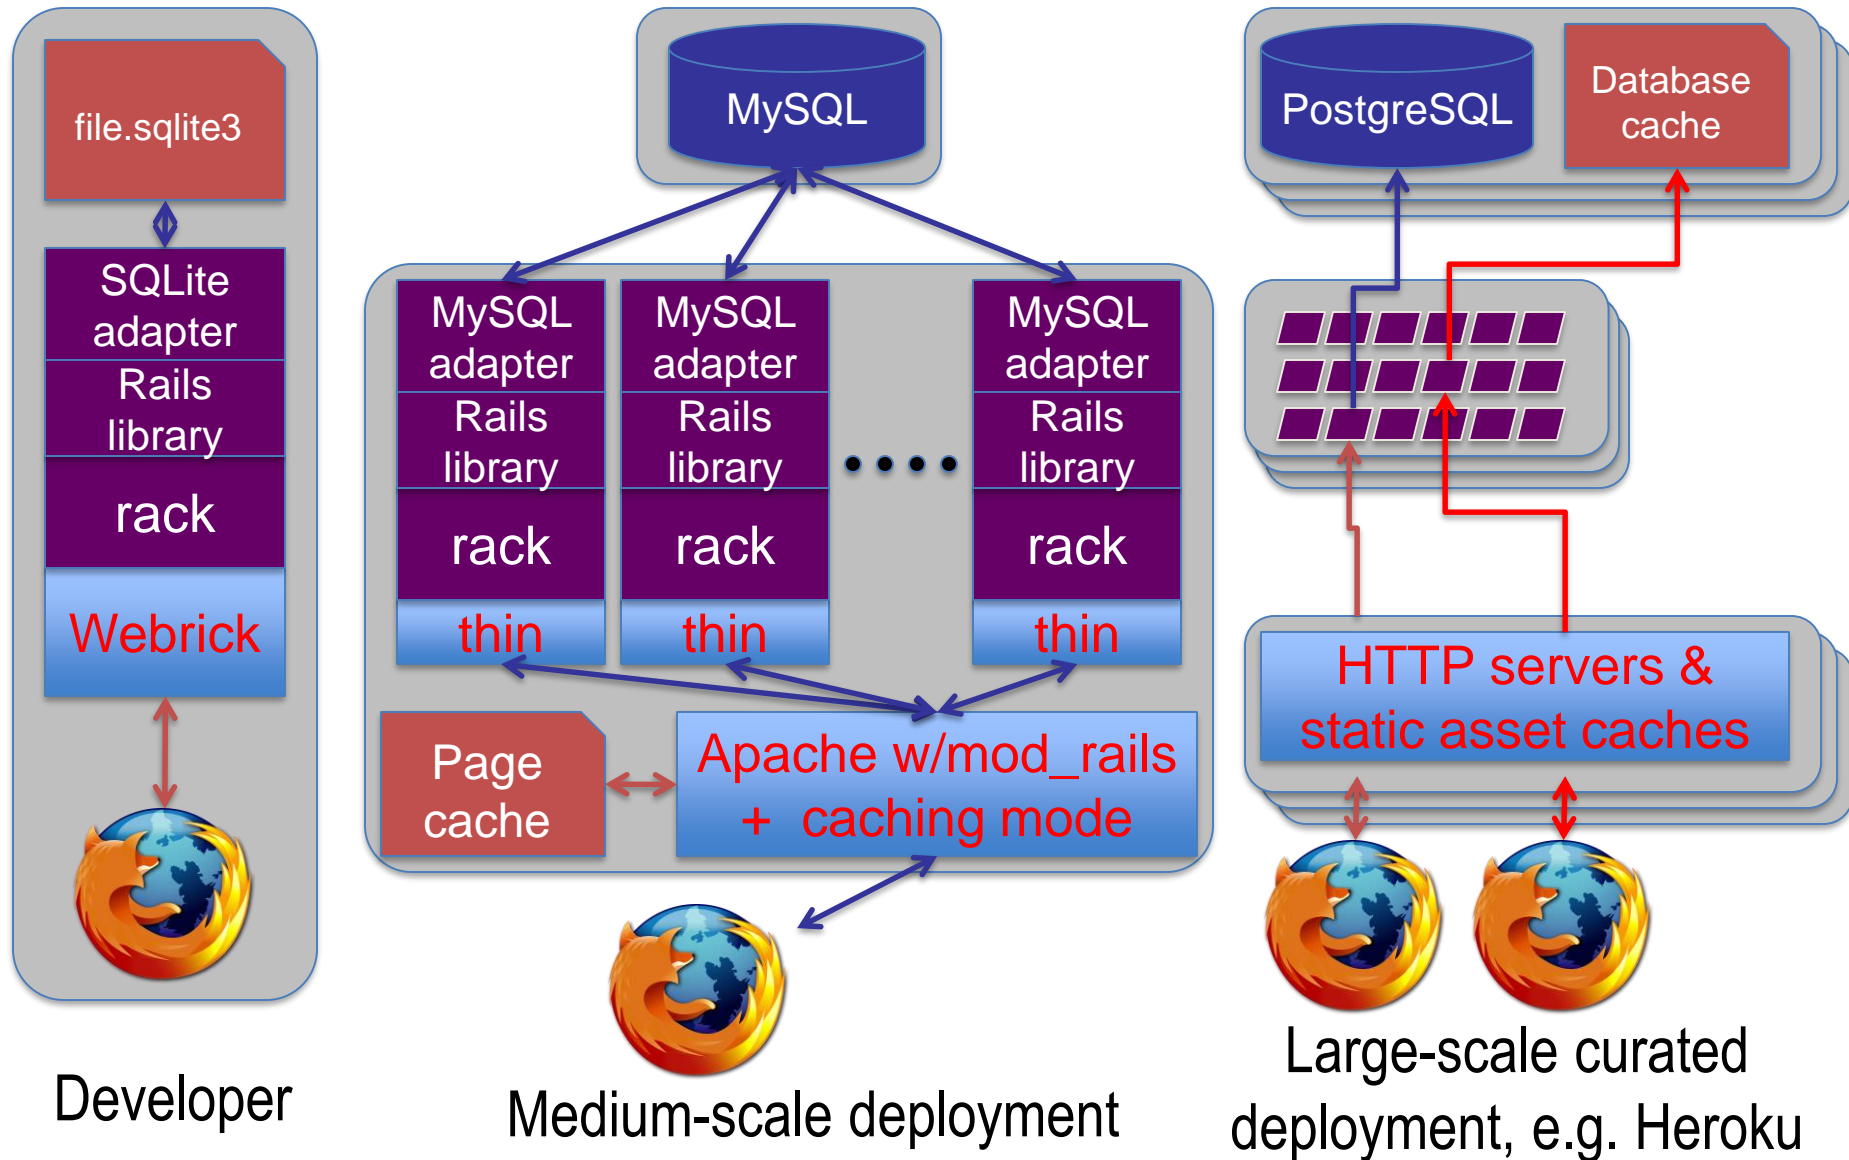

- How do you:
  - “map” URI to correct program & function?
  - pass arguments?
  - invoke program on server?
  - handle persistent storage?
  - handle cookies?
  - handle errors?
  - package output back to user?
- *Frameworks* support these common tasks
  - *Python Django*
  - *Node.js*

# Web Application Framework

- URL routing
- HTML, XML, JSON, and other output format templating
- Database manipulation
- Security against Cross-site request forgery (CSRF) and other attacks
- Session storage and retrieval

# Developer environment vs. medium-scale deployment

# “Shared nothing”

# Sharding vs. Replication

- Partition data across independent “shards”?
  - + Scales great
  - Bad when operations touch >1 table
  - Example use: user profile
- Replicate all data everywhere?
  - + Multi-table queries fast
  - Hard to scale: writes must propagate to all copies => temporary *inconsistency* in data values
  - Example: Facebook wall posts/“likes”

# Summary: Web SaaS

- Browser *requests* web resource (URI) using HTTP
  - HTTP is a simple request-reply protocol that relies on TCP/IP
  - In SaaS, most URI's cause a program to be run, rather than a static file to be fetched
- *HTML* is used to encode content, *CSS* to style it visually
- *Cookies* allow server to track client
- JavaScript, TypeScript, ...
- *Frameworks* make all these abstractions convenient for programmers to use, without sweating the details:  
Django, Angular, React/Redux
- Server-side frameworks help map SaaS to 3-tier, shared-nothing architecture
